(57) **ABSTRACT**

A wireless communication device configured for receiving multiple signals is described. The wireless communication device includes a single-chip carrier aggregation receiver architecture. The single-chip carrier aggregation receiver architecture includes a first antenna, a second antenna, a third antenna, a fourth antenna and a transceiver chip. The transceiver chip includes multiple carrier aggregation receivers. The single-chip carrier aggregation receiver architecture reuses at least one of the carrier aggregation receivers for secondary diversity.

**REUSING A SINGLE-CHIP CARRIER
AGGREGATION RECEIVER TO SUPPORT
NON-CELLULAR DIVERSITY**

TECHNICAL FIELD

The present disclosure relates generally to wireless devices for communication systems. More specifically, the present disclosure relates to systems and methods for a reusing a single-chip carrier aggregation receiver to support non-cellular diversity.

BACKGROUND

Electronic devices (cellular telephones, wireless modems, computers, digital music players, Global Positioning System units, Personal Digital Assistants, gaming devices, etc.) have become a part of everyday life. Small computing devices are now placed in everything from automobiles to housing locks. The complexity of electronic devices has increased dramatically in the last few years. For example, many electronic devices have one or more processors that help control the device, as well as a number of digital circuits to support the processor and other parts of the device.

These electronic devices may communicate wirelessly with each other and with a network. As the demand for information by these electronic devices has increased, the down-link throughput, as well as desired functionality, has also increased.

It may be desirable for an electronic device to maximize battery life. Because an electronic device often runs on a battery with a limited operation time, reductions in the power consumption of an electronic device may increase the desirability and functionality of the electronic device.

Electronic devices have also become smaller and cheaper. To facilitate both decrease in size and decrease in cost, additional circuitry and more complex circuitry are being used on integrated circuits. Thus, any reduction in the die area used by circuitry may reduce both the size and cost of an electronic device. Benefits may be realized by improvements to electronic devices that allow an electronic device to participate in reuse circuitry while minimizing the cost, size and/or power consumption of the electronic device.

SUMMARY

A wireless communication device configured for receiving multiple signals is described. The wireless communication device includes a single-chip carrier aggregation receiver architecture. The single-chip carrier aggregation receiver architecture includes a first antenna, a second antenna, a third antenna, a fourth antenna and a transceiver chip. The transceiver chip includes multiple carrier aggregation receivers. The single-chip carrier aggregation receiver architecture reuses at least one of the carrier aggregation receivers for secondary diversity.

The multiple carrier aggregation receivers may include a first receiver, a second receiver, a third receiver, and a fourth receiver. The transceiver chip may include a transmitter and a fifth receiver. The multiple carrier aggregation receivers may each include multiple low noise amplifiers. The fifth receiver may also include multiple low noise amplifiers.

The fifth receiver may be a non-carrier aggregation receiver, a non-simultaneous hybrid dual receiver, a global navigation satellite system receiver, a Bluetooth receiver or a Wi-Fi receiver.

2

A first secondary routing may be used from the third antenna through the fourth receiver to obtain a fourth Rx inphase/quadrature signal. A second secondary routing may be used from the fourth antenna through the fifth receiver to obtain a fifth Rx inphase/quadrature signal. The first secondary routing may pass through a first 4Rx low noise amplifier. The second secondary routing may pass through a first 5Rx low noise amplifier and a second 5Rx low noise amplifier.

The first receiver may include a first mixer. The second receiver may include a second mixer. The third receiver may include a third mixer. The fourth receiver may include a fourth mixer. The fifth receiver may include a fifth mixer.

The first secondary routing may pass through the fourth mixer. The fourth mixer may be driven by a voltage controlled oscillator on the second receiver and/or by a voltage controlled oscillator on the fifth receiver.

The wireless communication device may include a sixth mixer on the fourth receiver or the fifth receiver. The sixth mixer may be driven by a voltage controlled oscillator on the fifth receiver.

The first secondary routing may pass through a first 5RX low noise amplifier. The second secondary routing may pass through a second 5RX low noise amplifier.

The fourth Rx inphase/quadrature signal and the fifth Rx inphase/quadrature signal may pass through a baseband digital modem. The baseband digital modem may include a first analog-to-digital converter, a first baseband processor, a controller, a second analog-to-digital converter, a digital front end and a sample memory.

The first analog-to-digital converter may be a global navigation satellite system analog-to-digital converter. The controller may be a global navigation satellite system controller. The second analog-to-digital converter may be a wireless wideband area network analog-to-digital converter. The digital front end may be a wireless wideband area network digital front end. The sample memory may be a wideband area network sample memory.

The fourth Rx inphase/quadrature signal may pass through the first analog-to-digital converter, the first baseband processor and the controller. The fifth Rx inphase/quadrature signal may pass through the second analog-to-digital converter, the digital front end and the sample memory. The fifth Rx inphase/quadrature signal may pass through a third analog-to-digital converter, a second baseband processor and the controller.

The third analog-to-digital converter may be a global navigation satellite system analog-to-digital converter. The fourth Rx inphase/quadrature signal may pass through the first analog-to-digital converter, the first baseband processor and the controller. The fifth Rx inphase/quadrature signal may pass through the second analog-to-digital converter, the digital front end and the sample memory. The fifth Rx inphase/quadrature signal may pass through the second analog-to-digital converter, a second baseband processor and the controller.

The fourth Rx inphase/quadrature signal may pass through the first analog-to-digital converter, the first baseband processor and the controller. The fifth Rx inphase/quadrature signal may pass through the second analog-to-digital converter, the digital front end and the sample memory. The fifth Rx inphase/quadrature signal may pass through the second analog-to-digital converter, the digital front end, a second baseband processor and the controller.

The baseband digital modem may include a first analog-to-digital converter, a first digital front end, a controller, a second analog-to-digital converter, a second digital front end and a sample memory. The first analog-to-digital converter

may be a wireless wideband area network analog-to-digital converter. The first digital front end may be a wireless wideband area network digital front end. The controller may be a wireless wideband area network controller. The second analog-to-digital converter may be a wireless wideband area network analog-to-digital converter. The second digital front end may be a wireless wideband area network digital front end. The sample memory may be a wideband area network sample memory.

The fourth Rx inphase/quadrature signal may pass through the first analog-to-digital converter, the first digital front end and the controller. The fifth Rx inphase/quadrature signal may pass through the second analog-to-digital converter, the second digital front end and the sample memory. In another configuration, the fifth Rx inphase/quadrature signal may pass through a third analog-to-digital converter, a third digital front end and the controller. In yet another configuration, the fifth Rx inphase/quadrature signal may pass through the second analog-to-digital converter, a third digital front end and the controller. The fifth Rx inphase/quadrature signal may pass through the second analog-to-digital converter, the second digital front end and the controller.

A method for receiving multiple signals using a single-chip carrier aggregation receiver architecture that includes a first antenna, a second antenna, a third antenna and a fourth antenna is also described. A first secondary signal is received using the third antenna. The first secondary signal is routed through a fourth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture. The fourth receiver is one of multiple carrier aggregation receivers. The fourth receiver is reused for secondary diversity. A second secondary signal is received using the fourth antenna. The second secondary signal is routed through a fifth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture.

A computer-program product for receiving multiple signals using a single-chip carrier aggregation receiver architecture that includes a first antenna, a second antenna, a third antenna and a fourth antenna is described. The computer-program product includes a non-transitory computer-readable medium with instructions thereon. The instructions include code for causing a wireless communication device to receive a first secondary signal using the third antenna. The instructions also include code for causing the wireless communication device to route the first secondary signal through a fourth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture. The fourth receiver is one of multiple carrier aggregation receivers. The fourth receiver is reused for secondary diversity. The instructions further include code for causing the wireless communication device to receive a second secondary signal using the fourth antenna. The instructions also include code for causing the wireless communication device to route the second secondary signal through a fifth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture.

An apparatus for receiving multiple signals using a single-chip carrier aggregation receiver architecture that includes a first antenna, a second antenna, a third antenna and a fourth antenna is also described. The apparatus includes means for receiving a first secondary signal using the third antenna. The apparatus also includes means for routing the first secondary signal through a fourth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture. The fourth receiver is one of multiple carrier aggregation receivers. The fourth receiver is reused for secondary diversity. The apparatus further includes means for receiving a second secondary signal using the fourth antenna. The apparatus also

includes means for routing the second secondary signal through a fifth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a wireless communication device for use in the present systems and methods;

FIG. 2 is a block diagram illustrating a single-chip carrier aggregation receiver architecture operating in inter-band mode;

FIG. 3 is a block diagram illustrating a single-chip carrier aggregation receiver architecture;

FIG. 4 is a flow diagram of a method for receiving signals using a single-chip carrier aggregation receiver architecture;

FIG. 5 is a block diagram illustrating a single-chip carrier aggregation receiver architecture operating in diversity mode;

FIG. 6 is a block diagram illustrating a single-chip carrier aggregation receiver architecture that reuses a carrier aggregation receiver to achieve secondary diversity;

FIG. 7 is a block diagram illustrating a single-chip carrier aggregation receiver architecture that reuses a receiver front end and a baseband filter (BBF) of a carrier aggregation receiver to achieve secondary diversity;

FIG. 8 is a block diagram illustrating a single-chip carrier aggregation receiver architecture that reuses a baseband filter (BBF) of a carrier aggregation receiver to achieve secondary diversity;

FIG. 9 is a block diagram illustrating one configuration of a baseband digital modem used for secondary (e.g., global navigation satellite system (GNSS)) diversity;

FIG. 10 is a block diagram illustrating another configuration of a baseband digital modem used for secondary (e.g., global navigation satellite system (GNSS)) diversity;

FIG. 11 is a block diagram illustrating yet another configuration of a baseband digital modem used for secondary (e.g., global navigation satellite system (GNSS)) diversity;

FIG. 12 is a block diagram illustrating one configuration of a baseband digital modem used for secondary (e.g., wireless wide area network (WWAN)) diversity;

FIG. 13 is a block diagram illustrating another configuration of a baseband digital modem used for secondary (e.g., wireless wide area network (WWAN)) diversity;

FIG. 14 is a block diagram illustrating yet another configuration of a baseband digital modem used for secondary (e.g., wireless wide area network (WWAN)) diversity; and

FIG. 15 illustrates certain components that may be included within a wireless communication device.

DETAILED DESCRIPTION

The 3rd Generation Partnership Project (3GPP) is a collaboration between groups of telecommunications associations that aims to define a globally applicable 3rd generation (3G) mobile phone specification. 3GPP Long Term Evolution (LTE) is a 3GPP project aimed at improving the Universal Mobile Telecommunications System (UMTS) mobile phone standard. The 3GPP may define specifications for the next generation of mobile networks, mobile systems and mobile devices. In 3GPP LTE, a mobile station or device may be referred to as a “user equipment” (UE).

3GPP specifications are based on evolved Global System for Mobile Communications (GSM) specifications, which are generally known as the Universal Mobile Telecommunications System (UMTS). 3GPP standards are structured as releases. Discussion of 3GPP thus frequently refers to the

functionality in one release or another. For example, Release 99 specifies the first UMTS third generation (3G) networks, incorporating a CDMA air interface. Release 6 integrates operation with wireless local area networks (LAN) networks and adds High Speed Uplink Packet Access (HSUPA). Release 8 introduces dual downlink carriers and Release 9 extends dual carrier operation to uplink for UMTS.

CDMA2000 is a family of 3rd generation (3G) technology standards that use code division multiple access (CDMA) to send voice, data and signaling between wireless devices. CDMA2000 may include CDMA2000 1X, CDMA2000 EV-DO Rev. 0, CDMA2000 EV-DO Rev. A and CDMA2000 EV-DO Rev. B. 1x or 1xRTT refers to the core CDMA2000 wireless air interface standard. 1x more specifically refers to 1 times Radio Transmission Technology and indicates the same radio frequency (RF) bandwidth as used in IS-95. 1xRTT adds 64 additional traffic channels to the forward link. EV-DO refers to Evolution-Data Optimized. EV-DO is a telecommunications standard for the wireless transmission of data through radio signals.

FIG. 1 shows a wireless communication device **104** for use in the present systems and methods. A wireless communication device **104** may also be referred to as, and may include some or all of the functionality of, a terminal, an access terminal, a user equipment (UE), a subscriber unit, a station, etc. A wireless communication device **104** may be a cellular phone, a personal digital assistant (PDA), a wireless device, a wireless modem, a handheld device, a laptop computer, a PC card, compact flash, an external or internal modem, a wireline phone, etc. A wireless communication device **104** may be mobile or stationary. A wireless communication device **104** may communicate with zero, one or multiple base stations on a downlink and/or an uplink at any given moment. The downlink (or forward link) refers to the communication link from a base station to a wireless communication device **104** and the uplink (or reverse link) refers to the communication link from a wireless communication device **104** to a base station. Uplink and downlink may refer to the communication link or to the carriers used for the communication link.

A wireless communication device **104** may operate in a wireless communication system that includes other wireless devices, such as base stations. A base station is a station that communicates with one or more wireless communication devices **104**. A base station may also be referred to as, and may include some or all of the functionality of, an access point, a broadcast transmitter, a Node B, an evolved Node B, etc. Each base station provides communication coverage for a particular geographic area. A base station may provide communication coverage for one or more wireless communication devices **104**. The term "cell" can refer to a base station and/or its coverage area, depending on the context in which the term is used.

The wireless communication device **104** may include a first antenna **106**, a second antenna **108**, a third antenna **107** and a fourth antenna **109**. In some configurations, the fourth antenna **109** may be a dedicated antenna for sending and/or receiving data on a third band. For example, the fourth antenna **109** may be a dedicated global positioning system (GPS) or Wi-Fi antenna. In some configurations, the third antenna **107** may also be used for sending and/or receiving data on a third band when not used for carrier aggregation. In this manner, the third antenna **107** and the fourth antenna **109** may be used to achieve diversity of the third band. As used herein, diversity refers to using two or more antennas to improve the quality and reliability of a wireless link. For example, if a third band is a Wi-Fi band, then secondary diversity refers to improving the quality and reliability of the

Wi-Fi signal by using both the third antenna **107** and the fourth antenna **109** to receive the Wi-Fi signal.

Communications in a wireless communication system (e.g., a multiple-access system) may be achieved through transmissions over a wireless link. Such a communication link may be established via a single-input and single-output (SISO) or a multiple-input and multiple-output (MIMO) system. A multiple-input and multiple-output (MIMO) system includes transmitter(s) and receiver(s) equipped, respectively, with multiple (NT) transmit antennas and multiple (NR) receive antennas for data transmission. SISO systems are particular instances of a multiple-input and multiple-output (MIMO) system. The multiple-input and multiple-output (MIMO) system can provide improved performance (e.g., higher throughput, greater capacity or improved reliability) if the additional dimensionalities created by the multiple transmit and receive antennas are utilized.

The wireless communication system may utilize both single-input and multiple-output (SIMO) and multiple-input and multiple-output (MIMO). The wireless communication system may be a multiple-access system capable of supporting communication with multiple wireless communication devices **104** by sharing the available system resources (e.g., bandwidth and transmit power). Examples of such multiple-access systems include code division multiple access (CDMA) systems, wideband code division multiple access (W-CDMA) systems, time division multiple access (TDMA) systems, frequency division multiple access (FDMA) systems, orthogonal frequency division multiple access (OFDMA) systems, single-carrier frequency division multiple access (SC-FDMA) systems, 3rd Generation Partnership Project (3GPP) Long Term Evolution (LTE) systems and spatial division multiple access (SDMA) systems.

A transceiver chip **110** may be coupled to the first antenna **106**, the second antenna **108**, the third antenna **107** and the fourth antenna **109**. The transceiver chip **110** may include a transmitter and multiple carrier aggregation receivers. The multiple carrier aggregation receivers may include a first receiver (1Rx) **140**, a second receiver (2Rx) **142**, a third receiver (3Rx) **144** and a fourth receiver (4Rx) **146**. The transceiver chip **110** may include a secondary transmitter and a fifth receiver (5Rx) **147**.

When operating in non-simultaneous hybrid dual receiver (SHDR) mode and/or non-carrier aggregation mode, the third receiver (3Rx) **144** and/or fourth receiver (4Rx) **146** may be idle. In other words, the third receiver (3Rx) **144** and/or fourth receiver (4Rx) **146** may be unused for non-simultaneous hybrid dual receiver (SHDR) operation and/or non-carrier aggregation operation of the wireless communication device **104**. In this case, the third receiver (3Rx) **144** and/or fourth receiver (4Rx) **146** may be reused for secondary diversity. By using the third receiver (3Rx) **144** and/or fourth receiver (4Rx) **146** for secondary diversity, the wireless communication device **104** may be able to employ secondary diversity of a third band (e.g., a non-cellular band) without requiring an additional antenna or circuitry. By using additional antennas and/or receivers for the third band, the multiple-input and multiple-output (MIMO) capabilities of the third band may be expanded. In other words, the quality and reliability of the third band may be improved. For example, if the third band corresponds to global positioning system (GPS) or Wi-Fi, reusing the third antenna **107** along with the corresponding fourth receiver (4Rx) **146**, in addition to the fourth antenna **109** and corresponding fifth receiver (5Rx) **147**, will increase the multiple-input and multiple-output (MIMO) capabilities of the global positioning system (GPS) or Wi-Fi.

In some configurations, the first antenna **106** may be a primary antenna and the first receiver (1Rx) **140** may be a primary receiver. The second antenna **108** may be a secondary antenna and the second receiver (2Rx) **142** may be a secondary receiver. The third antenna **107** may be a tertiary antenna and the third receiver (3Rx) **144** may be a tertiary receiver. The fourth antenna **109** may be a quaternary antenna and the fourth receiver (4Rx) **146** may be a quaternary receiver. The fifth receiver (5Rx) **147** may be a secondary receiver. For example, the fifth receiver (5Rx) **147** may be a non-simultaneous hybrid diversity receiver (SHDR) receiver, a non-carrier aggregation receiver or another type of non-cellular technology receiver. For instance, the fifth receiver (5Rx) **147** may be a global navigation satellite system (GNSS), global positioning system (GPS), Wi-Fi (e.g., wireless local area network (WLAN)) or Bluetooth receiver.

The first receiver (1Rx) **140** of the transceiver chip **110** may output a 1Rx inphase/quadrature (I/Q) signal **112** to a baseband digital modem **122** on the wireless communication device **104**. The second receiver (2Rx) **142** of the transceiver chip **110** may output a 2Rx inphase/quadrature (I/Q) signal **114** to the baseband digital modem **122**. The third receiver (3Rx) **144** of the transceiver chip **110** may output a 3Rx inphase/quadrature (I/Q) signal **116** to the baseband digital modem **122**. The fourth receiver (4Rx) **146** of the transceiver chip **110** may output a 4Rx inphase/quadrature (I/Q) signal **118** to the baseband digital modem **122**. The 1Rx inphase/quadrature (I/Q) signal **112**, 2Rx inphase/quadrature (I/Q) signal **114**, 3Rx inphase/quadrature (I/Q) signal **116** and 4Rx inphase/quadrature (I/Q) signal **118** may correspond to carrier aggregation signals.

The fifth receiver (5Rx) **147** of the transceiver chip **110** may output a 5Rx inphase/quadrature (I/Q) signal **119** to the baseband digital modem **122**. The 5Rx inphase/quadrature (I/Q) signal **119** may correspond to a secondary signal. In some configurations, such as in secondary diversity mode, the 5Rx inphase/quadrature (I/Q) signal **119** may be referred to as a secondary signal.

In some configurations, the wireless communication device **104** may use a single-chip carrier aggregation receiver architecture **125** that reuses one or more of the carrier aggregation receivers (e.g., the third receiver (3Rx) **144** and fourth receiver (4Rx) **146**) for secondary diversity. Secondary diversity may include the single-chip carrier aggregation receiver architecture **125** operating in non-simultaneous hybrid dual receiver (SHDR) mode and/or non-carrier aggregation mode. In this manner, the single-chip carrier aggregation receiver architecture **125** may be reused to improve the quality and reliability of receiving and processing the secondary signal. For example, if a secondary signal is a Wi-Fi band, then secondary diversity may improve the quality and reliability of the Wi-Fi signal by reusing parts of the transceiver chip **110** to receive the Wi-Fi signal.

The baseband digital modem **122** may perform processing on the 1Rx inphase/quadrature (I/Q) signal **112**, the 2Rx inphase/quadrature (I/Q) signal **114**, the 3Rx inphase/quadrature (I/Q) signal **116**, the 4Rx inphase/quadrature (I/Q) signal **118** and the 5Rx inphase/quadrature (I/Q) signal **119**. For example, the baseband digital modem **122** may convert the signals to the digital domain using analog-to-digital converters (ADCs) and perform digital processing on the signals using digital signal processors (DSPs). The baseband digital modem **122** may then output a first carrier signal **124a**, a second carrier signal **124b**, a third carrier signal **124c**, a fourth carrier signal **124d** and a fifth carrier signal **124e**. A carrier signal **124** may refer to the carrier that the signal used.

In one configuration, the first carrier signal **124a** and the second carrier signal **124b** may be located in a low band while the third carrier signal **124c** and the fourth carrier signal **124d** are located within a midband. This may be referred to as inter-band operation or Dual-Band 4-Carrier according to Rel-10. In another configuration, the first carrier signal **124a**, second carrier signal **124b**, third carrier signal **124c** and fourth carrier signal **124d** may all be located within a single band, such as the low band. This may be referred to as intra-band operation or Single-Band 4-Carrier in Release-10. In some configurations the fifth carrier signal **124e** may be located within a third band. For example, the third band may be a global navigation satellite system (GNSS), a global positioning system (GPS) or a Wi-Fi band.

FIG. 2 is a block diagram illustrating a single-chip carrier aggregation receiver architecture **225**. The single-chip carrier aggregation receiver architecture **225** of FIG. 2 may be one configuration of the single-chip carrier aggregation receiver architecture **125** of FIG. 1. The single-chip carrier aggregation receiver architecture **225** may include a first antenna **206**, a second antenna **208**, a third antenna **207**, a fourth antenna **209** and a transceiver chip **210**. The first antenna **206** and the second antenna **208** may be used to receive a dual-band 4-carrier signal (i.e., four carriers **274a-d** over a first band **270** and a second band **272** (the first band **270** and the second band **272** are separated from each other)).

The transceiver chip **210** may include a transmitter **232**, a first receiver (1Rx) **240**, a second receiver (2Rx) **242**, a third receiver (3Rx) **244**, a fourth receiver (4Rx) **246** and a fifth (5Rx) receiver **247**. The first antenna **206** may be coupled to 1Rx circuitry **268a** of the first receiver (1Rx) **240**. The 1Rx circuitry **268a** may include 1Rx low noise amplifiers (LNAs), downconverting circuitry and a 1Rx baseband filter (BBF). The 1Rx circuitry **268a** may output a 1Rx inphase/quadrature (I/Q) signal **212** that includes the first carrier **274a** and the second carrier **274b** in the first band **270**. As used herein, source low noise amplifier (LNA) refers to a low noise amplifier (LNA) from which a signal routing is taken and target low noise amplifier (LNA) refers to a low noise amplifier (LNA) to which the signal routing is directed.

The second antenna **208** may be coupled to 2Rx circuitry **268b** of the second receiver (2Rx) **242**. The 2Rx circuitry **268b** may include 2Rx low noise amplifiers (LNAs), downconverting circuitry and a 2Rx baseband filter (BBF). The 2Rx circuitry **268b** may output a 2Rx inphase/quadrature (I/Q) signal **214** that includes the first carrier **274a** and the second carrier **274b** in the first band **270**.

In some configurations, the third antenna **207** may be coupled to 4Rx circuitry **268d** of the fourth receiver (4Rx) **246**. The 4Rx circuitry **268d** may include 4Rx low noise amplifiers (LNAs), downconverting circuitry and a 4Rx baseband filter (BBF). The 4Rx circuitry **268d** may output a 4Rx inphase/quadrature (I/Q) signal **218** that includes the secondary signal **278** in the third band **276**. In other configurations, the fourth receiver (4Rx) **246** is idle and not used for carrier aggregation.

In some configurations, the third antenna **207** may be used to receive a secondary signal **278** (i.e., a secondary signal **278** over a third band **276**). For example, the third antenna **207** may receive a first secondary signal. For instance, the third band **276** may be a global navigation satellite system (GNSS) band, a global positioning system (GPS) band, a Wi-Fi band or some other type of band. In this configuration, the 4Rx circuitry **268d** may output a 4Rx inphase/quadrature (I/Q) signal **218** that includes the secondary signal **278** in the third band **276**.

The fourth antenna **209** may be used to receive a secondary signal **278**. For example, the fourth antenna **209** may also receive the secondary signal **278** (e.g., a second secondary signal **278**). The fourth antenna **209** may be coupled to 5Rx circuitry **268e** of the fifth receiver (5Rx) **247**. The 5Rx circuitry **268e** may include 5Rx low noise amplifiers (LNAs), downconverting circuitry and a 5Rx baseband filter (BBF). The 5Rx circuitry **268e** may output a 5Rx inphase/quadrature (I/Q) signal **219** that includes the secondary signal **278** in the third band **276**.

In some configurations, the third antenna **207** may be used to receive one type of secondary signal **278**, such as a global positioning system (GPS) signal, while the fourth antenna **209** may be used to receive another type of secondary signal **278**, such as a Wi-Fi signal. Thus, in this configuration, the idle fourth receiver (4Rx) **246** may be used to achieve one type of non-cellular secondary diversity, while the fifth receiver (5Rx) **247** may be used to achieve another type of non-cellular secondary diversity.

FIG. **3** is a block diagram illustrating a single-chip carrier aggregation receiver architecture **325**. The single-chip carrier aggregation receiver architecture **325** of FIG. **3** may be one configuration of the single-chip carrier aggregation receiver architecture **125** of FIG. **1**. The single-chip carrier aggregation receiver architecture **325** may include a first antenna **306**, a first low-pass high-pass diplexer **326a**, a first switch **328a**, four duplexers **330a-d**, a second antenna **308**, a second low-pass high-pass diplexer **326b**, a second switch **328b**, six surface acoustic wave (SAW) filters **334a-f**, a third antenna **307**, a fourth antenna **309** and a transceiver chip **310**.

The first antenna **306** may be coupled to the first low-pass high-pass diplexer **326a**. A low-pass high-pass diplexer **326** may bundle low band frequencies into one signal and high band (or midband) frequencies into another signal, thus allowing the first antenna **306** to pass both low band and midband signals to the transceiver chip **310**. The first low-pass high-pass diplexer **326a** may be coupled to the first switch **328a**. The first switch **328a** may have two inputs (the signal that includes the bundled low band frequencies and the signal that includes the bundled high band frequencies) and multiple outputs. In one configuration, the first switch **328a** may have six possible outputs to the four duplexers **330** (representing the six possible configurations of duplexer **330** pairs). The four duplexers **330** may include a first duplexer **330a**, a second duplexer **330b**, a third duplexer **330c** and a fourth duplexer **330d**. In one configuration, the first duplexer **330a** and the second duplexer **330b** may be used for a low band while the third duplexer **330c** and the fourth duplexer **330d** are used for a midband.

The transceiver chip **310** may include a transmitter **332** and carrier aggregation receivers. The carrier aggregation receivers may include a first receiver (1Rx) **340**, a second receiver (2Rx) **342**, a third receiver (3Rx) **344** and a fourth receiver (4Rx) **346**. The transceiver chip **310** may also include a fifth receiver (5Rx) **347**. The fifth receiver (5Rx) **347** may be a primary receiver for a secondary signal **278**. It should be noted that the transceiver chip **310** may include a second transmitter (not shown) for transmitting on the third band **276**. The secondary transmitter may function similarly to the transmitter **332** described below or other types of transmitters known in the art. However, for the purpose of simplicity, the secondary transmitter is not shown in FIG. **3**. The secondary transmitter may correspond to Wi-Fi, Bluetooth or another type on non-cellular technology.

The transmitter **332** may include four transmit outputs: a first transmit output, a second transmit output, a third transmit output and a fourth transmit output. In one configuration, the

first transmit output and the second transmit output may be first band outputs while the third transmit output and the fourth transmit output may be second band outputs. In another configuration, the third transmit output and/or the fourth transmit output may be third band outputs.

The first transmit output may be coupled to the first duplexer **330a** via a power amplifier (PA) **338a**. The second transmit output may be coupled to the second duplexer **330b** via a power amplifier **338b**. The third transmit output may be coupled to the third duplexer **330c** via a power amplifier **338c**. The fourth transmit output may be coupled to the fourth duplexer **330d** via a power amplifier **338d**.

The first receiver (1Rx) **340** may include a first 1Rx low noise amplifier (LNA) **348a** coupled to the first duplexer **330a**, a second 1Rx low noise amplifier (LNA) **348b** coupled to the second duplexer **330b**, a third 1Rx low noise amplifier (LNA) **348c** coupled to the third duplexer **330c** and a fourth 1Rx low noise amplifier (LNA) **348d** coupled to the fourth duplexer **330d**. In one configuration, the first 1Rx low noise amplifier (LNA) **348a** and the second 1Rx low noise amplifier (LNA) **348b** may be low band low noise amplifiers (LNAs) while the third 1Rx low noise amplifier (LNA) **348c** and the fourth 1Rx low noise amplifier (LNA) **348d** are midband low noise amplifiers (LNAs).

In another configuration, the first 1Rx low noise amplifier (LNA) **348a** and the second 1Rx low noise amplifier (LNA) **348b** may be first band **270** low noise amplifiers (LNAs) while the third 1Rx low noise amplifier (LNA) **348c** and the fourth 1Rx low noise amplifier (LNA) **348d** are second band **272** low noise amplifiers (LNAs). The first 5Rx low noise amplifier (LNA) **355a** may be third band **276** low noise amplifiers (LNAs).

The first receiver (1Rx) **340** may also include a mixer **356a** (e.g., a downconverter). The mixer **356a** may be coupled to the output of the first 1Rx low noise amplifier (LNA) **348a**, the output of the second 1Rx low noise amplifier (LNA) **348b**, the output of the third 1Rx low noise amplifier (LNA) **348c** and the output of the fourth 1Rx low noise amplifier (LNA) **348d**.

The first receiver (1Rx) **340** may include a phase locked loop (PLL) **362a**, a 1Rx voltage controlled oscillator (VCO) **360** and a Div stage **358a** that are used to generate the downconverting frequency for the mixer **356a**. The output of the mixer **356a** may be coupled to a 1Rx baseband filter (BBF) **364a**. The 1Rx baseband filter (BBF) **364a** may then output the 1Rx inphase/quadrature (I/Q) signal **312**. The transceiver chip **310** may include a switch **366** that allows the downconverting frequency generated by the 1Rx voltage controlled oscillator (VCO) **360** to be used by a mixer **356b** in the second receiver (2Rx) **342**, a mixer **356c** in the third receiver (3Rx) **344** and/or a mixer **356d** in the fourth receiver (4Rx) **346**.

The second antenna **308** may be coupled to the second low-pass high-pass diplexer **326b**. The second low-pass high-pass diplexer **326b** may be coupled to the second switch **328b**. The second switch **328b** may have two inputs (the signal that includes the bundled low band frequencies and the signal that includes the bundled high band frequencies) and multiple outputs. In one configuration, the second switch **328b** may have six possible outputs to four surface acoustic wave (SAW) filters **334a-d** (representing the six possible configurations of surface acoustic wave (SAW) filter **334a-d** pairs). The four surface acoustic wave (SAW) filters **334a-d** may include a first surface acoustic wave (SAW) filter **334a**, a second surface acoustic wave (SAW) filter **334b**, a third surface acoustic wave (SAW) filter **334c** and a fourth surface acoustic wave (SAW) filter **334d**.

The second receiver (2Rx) **342** may include a first 2Rx low noise amplifier (LNA) **350a** coupled to the first surface acoustic wave (SAW) filter **334a**, a second 2Rx low noise amplifier (LNA) **350b** coupled to the second surface acoustic wave (SAW) filter **334b**, a third 2Rx low noise amplifier (LNA) **350c** coupled to the third surface acoustic wave (SAW) filter **334c** and a fourth 2Rx low noise amplifier (LNA) **350d** coupled to the fourth surface acoustic wave (SAW) filter **334d**.

The second receiver (2Rx) **342** may include a mixer **356b** coupled to the output of the first 2Rx low noise amplifier (LNA) **350a**, the output of the second 2Rx low noise amplifier (LNA) **350b**, the output of the third 2Rx low noise amplifier (LNA) **350c** and the output of the fourth 2Rx low noise amplifier (LNA) **350d**. The second receiver (2Rx) **342** may also include a phase locked loop (PLL) **362b**, a 2Rx voltage controlled oscillator (VCO) **361** and a Div stage **358b** that are used to generate a downconverting frequency for the mixer **356b**. In one configuration, the switch **366** on the transceiver chip **310** may be set so that the Div stage **358b** receives the downconverting frequency generated by the 1Rx voltage controlled oscillator (VCO) **360** from the first receiver (1Rx) **340**. The output of the mixer **356b** may be coupled to a 2Rx baseband filter (BBF) **364b**. The 2Rx baseband filter (BBF) **364b** may then output the 2Rx inphase/quadrature (I/Q) signal **314**.

The switch **366** allows the downconverting frequency generated by the 2Rx voltage controlled oscillator (VCO) **361** to be used by a mixer **356c** in the third receiver (3Rx) **344** and a mixer **356d** in the fourth receiver (4Rx) **346**. The 2Rx voltage controlled oscillator (VCO) **361** may be used for the third receiver (3Rx) **344** and/or fourth receiver (4Rx) **346** in non-carrier aggregation, non-simultaneous hybrid dual receiver (SHDR) mode. Otherwise, the 2Rx voltage controlled oscillator (VCO) **361** may be idle.

When used in non-carrier aggregation, non-simultaneous hybrid dual receiver (SHDR) mode, the 2Rx voltage controlled oscillator (VCO) **361** may be tuned to a secondary frequency to drive secondary diversity. For example, the secondary frequency may be a Personal Digital Cellular (PDC) band around 1.5 gigahertz (GHz) used for global positioning system (GPS). Thus, in this example, the 2Rx voltage controlled oscillator (VCO) **361** may be tuned to around 1.5 GHz and may be used to drive the fourth receiver (4Rx) **346**. As a result, the fourth receiver (4Rx) **346** may be reused to support the Personal Digital Cellular (PDC) band. The 4Rx inphase/quadrature (I/Q) signal **318** and the 5Rx inphase/quadrature (I/Q) signal **319** may then be combined for secondary diversity. In other words, the fourth receiver (4Rx) **346** inphase/quadrature (I/Q) signal **318** may be added to the fifth receiver (5Rx) **347** inphase/quadrature (I/Q) signal **319** to increase and/or expand the multiple-input and multiple-output (MIMO) capabilities of the third band **276**.

In another example, the secondary frequency may be an unlicensed band around 2.4 gigahertz (GHz) used for Wi-Fi and/or Bluetooth. Thus, in this example, the 2Rx voltage controlled oscillator (VCO) **361** may be tuned to around 2.4 GHz and may be used to drive the fourth receiver (4Rx) **346**. As a result, the fourth receiver (4Rx) **346** may be reused to support Wi-Fi and/or Bluetooth around 2.4 GHz. In some configurations, the 4Rx inphase/quadrature (I/Q) signal **318** and the 5Rx inphase/quadrature (I/Q) signal **319** may then be combined for secondary diversity, such as both employing Wi-Fi diversity. The 4Rx inphase/quadrature (I/Q) signal **318** and the 5Rx inphase/quadrature (I/Q) signal **319** may each

inphase/quadrature (I/Q) signal **318** corresponding to Wi-Fi while the 5Rx inphase/quadrature (I/Q) signal **319** corresponding to Bluetooth.

The third receiver (3Rx) **344** may include a first 3Rx low noise amplifier (LNA) **352a**, a second 3Rx low noise amplifier (LNA) **352b**, a third 3Rx low noise amplifier (LNA) **352c** and a fourth 3Rx low noise amplifier (LNA) **352d**. The inputs to the first 3Rx low noise amplifier (LNA) **352a**, the second 3Rx low noise amplifier (LNA) **352b**, the third 3Rx low noise amplifier (LNA) **352c** and the fourth 3Rx low noise amplifier (LNA) **352d** may be disabled.

The third receiver (3Rx) **344** may include a mixer **356c** coupled to the outputs of the first 3Rx low noise amplifier (LNA) **352a**, the second 3Rx low noise amplifier (LNA) **352b**, the third 3Rx low noise amplifier (LNA) **352c** and the fourth 3Rx low noise amplifier (LNA) **352d**. The third receiver (3Rx) **344** may also include a Div stage **358c** coupled to the mixer **356c**. The Div stage **358c** may be coupled to the switch **366** on the transceiver chip **310**. In one configuration, the switch **366** may be set so that the Div stage **358c** may receive the downconverting frequency generated by the 1Rx voltage controlled oscillator (VCO) **360** from the first receiver (1Rx) **340**. In another configuration, the switch **366** may be set so that the Div stage **358c** receives the downconverting frequency generated by the 2Rx voltage controlled oscillator (VCO) **361**. In some configurations, such as in non-carrier aggregation mode and/or non-simultaneous hybrid dual receiver (SHDR) mode, the third receiver (3Rx) **344** may remain idle and unused or reused for secondary diversity. The output of the mixer **356c** may be coupled to a 3Rx baseband filter (BBF) **364c**. The 3Rx baseband filter (BBF) **364c** may then output the 3Rx inphase/quadrature (I/Q) signal **316**.

The fourth receiver (4Rx) **346** may include a first 4Rx low noise amplifier (LNA) **354a**, a second 4Rx low noise amplifier (LNA) **354b**, a third 4Rx low noise amplifier (LNA) **354c** and a fourth 4Rx low noise amplifier (LNA) **354d**. The inputs to the first 4Rx low noise amplifier (LNA) **354a**, the second 4Rx low noise amplifier (LNA) **354b**, the third 4Rx low noise amplifier (LNA) **354c** and the fourth 4Rx low noise amplifier (LNA) **354d** may be disabled. In some configurations, one or more of the 4Rx low noise amplifier (LNAs) **354** may receive input from a fifth surface acoustic wave (SAW) filter **334e** coupled to the third antenna **307**. For example, the third antenna **307** may provide a signal to the third 4Rx low noise amplifier (LNA) **354c** via the fifth surface acoustic wave (SAW) filter **334e**.

The fourth receiver (4Rx) **346** may include a mixer **356d** coupled to the outputs of the first 4Rx low noise amplifier (LNA) **354a**, the second 4Rx low noise amplifier (LNA) **354b**, the third 4Rx low noise amplifier (LNA) **354c** and the fourth 4Rx low noise amplifier (LNA) **354d**. The fourth receiver (4Rx) **346** may also include a Div stage **358d** coupled to the mixer **356d**. The Div stage **358d** may be coupled to the switch **366** on the transceiver chip **310**. In one configuration, the switch **366** may be set so that the Div stage **358d** may receive the downconverting frequency generated by the 1Rx voltage controlled oscillator (VCO) **360** from the first receiver (1Rx) **340**. In another configuration, such as in non-carrier aggregation mode and/or non-simultaneous hybrid dual receiver (SHDR) mode, the fourth receiver (4Rx) **346** may remain idle and unused. The output of the mixer **356d** may be coupled to a 4Rx baseband filter (BBF) **364d**. The 4Rx baseband filter (BBF) **364d** may then output the 4Rx inphase/quadrature (I/Q) signal **318**.

In one configuration, the switch **366** may be set so that the Div stage **358d** of the fourth receiver (4Rx) **346** receives the

downconverting frequency generated by the 2Rx voltage controlled oscillator (VCO) **361** from the second receiver (2Rx) **342**. For example, the 2Rx voltage controlled oscillator (VCO) **361** from the second receiver (2Rx) **342** may be tuned to the secondary frequency to drive secondary diversity for the fourth receiver (4Rx) **346**.

The fourth antenna **309** may be coupled to a sixth surface acoustic wave (SAW) filter **334f**. The sixth surface acoustic wave (SAW) filter **334f** may be coupled to the fifth receiver (5Rx) **347**. The fifth receiver (5Rx) **347** may include a first 5Rx low noise amplifier (LNA) **355a**.

The fifth receiver (5Rx) **344** may also include a mixer **356e** (e.g., a downconverter). The mixer **356e** may be coupled to the output of the first 5Rx low noise amplifier (LNA) **355a**.

The fifth receiver (5Rx) **347** may include a phase locked loop (PLL) **362c**, a 5Rx voltage controlled oscillator (VCO) **363** and a Div stage **358e** that are used to generate the downconverting frequency for the mixer **356e**. The output of the mixer **356e** may be coupled to a 5Rx baseband filter (BBF) **364e**. The 5Rx baseband filter (BBF) **364e** may then output the 5Rx inphase/quadrature (I/Q) signal **319**. The 5Rx inphase/quadrature (I/Q) signal **319** may be a secondary signal such as a global navigation satellite system (GNSS), a global positioning system (GPS) or a Wi-Fi signal.

FIG. 4 is a flow diagram of a method **400** for receiving signals using a single-chip carrier aggregation receiver architecture **125**. The method **400** may be performed by a wireless communication device **104**. The wireless communication device **104** may receive **402** a first secondary signal using the third antenna **107**. The wireless communication device **104** may route **404** the first secondary signal through a fourth receiver (4Rx) **146** on a transceiver chip **110** to obtain a 4Rx inphase/quadrature (I/Q) signal **118**.

The wireless communication device **104** may also receive **406** a second secondary signal using the fourth antenna **109**. The wireless communication device **104** may route **408** the second secondary signal through a fifth receiver (5Rx) **147** on the transceiver chip **110** to obtain a 5Rx inphase/quadrature (I/Q) signal **119**. The first secondary signal and the second secondary signal may be from the same band (e.g., the third band **276**). For instance, the third band **276** may be a global navigation satellite system (GNSS) band, a global positioning system (GPS) band, a Wi-Fi band or some other type of band.

FIG. 5 is a block diagram illustrating a single-chip carrier aggregation receiver architecture **325** operating in diversity mode. The single-chip carrier aggregation receiver architecture **325** of FIG. 5 may be the single-chip carrier aggregation receiver architecture **325** of FIG. 3.

A routing **537** from the first antenna **306** through the first receiver (1Rx) **340** to obtain the 1Rx inphase/quadrature (I/Q) signal **314** is shown. The routing **537** may pass through the first 1Rx low noise amplifier (LNA) **348a**. The 1Rx inphase/quadrature (I/Q) signal **314** may include a first carrier **274a** and a second carrier **274b** from a first band **270** for this configuration. The routing **537** may pass through the mixer **356b**. The mixer **356b** may receive input from the Div stage **358b**. The switch **366** on the transceiver chip **310** may be set so that the Div stage **358b** receives the downconverting frequency generated by the 1Rx voltage controlled oscillator (VCO) **360** from the first receiver (1Rx) **340**. In this manner, the 2Rx voltage controlled oscillator (VCO) **361** from the second receiver (2Rx) **342** may be used with the third receiver (3Rx) **344** and/or the fourth receiver (4Rx) **346**.

A routing **539** from the second antenna **308** through the second receiver (2Rx) **342** to obtain the 2Rx inphase/quadrature (I/Q) signal **316** is also shown. The routing **539** may pass through the first 2Rx low noise amplifier (LNA) **350a**. The

2Rx inphase/quadrature (I/Q) signal **314** may include a first carrier **274a** and a second carrier **274b** from the first band **270** for this configuration.

Is some configurations, such as when a simultaneous hybrid dual receiver (SHDR) receiver path is not employed by the transceiver chip **310**, the third receiver (3Rx) **344** and/or the fourth receiver (4Rx) **346** may be reused for secondary diversity. For example, the fourth receiver (4Rx) **346** may be a carrier aggregation receiver. When not used for carrier aggregation, the fourth receiver (4Rx) **346** may be reused for secondary diversity.

A routing **541** from the third antenna **307** through the fourth receiver (4Rx) **346** to obtain the 4Rx inphase/quadrature (I/Q) signal **318** is also shown. The routing **541** may be referred to as a first secondary routing. For example, the first secondary routing may correspond to a non-cellular signal such as a global positioning system (GPS) or Wi-Fi signal. The routing **541** may pass through the third 4Rx low noise amplifier (LNA) **354c**. In some configurations, an additional transconductance stage (Gm) may be added to the fourth receiver (4Rx) **346** path to support secondary diversity and to avoid additional switches.

The routing **541** may pass through the mixer **356d**. The mixer **356d** may receive input from the Div stage **358d**. The switch **366** on the transceiver chip **310** may be set so that the Div stage **358d** receives the downconverting frequency generated by the 2Rx voltage controlled oscillator (VCO) **361** from the second receiver (2Rx) **342**. In other words, the 2Rx voltage controlled oscillator (VCO) **361** from the second receiver (2Rx) **342** is be used to drive the Div stage **358d** and mixer **356d** of the fourth receiver (4Rx) **346** rather than being used to drive the Div stage **358b** and mixer **356b** of the second receiver (2Rx) **342**. The output of the mixer **356d** may pass through the 4Rx baseband filter (BBF) **364d** to form a 4Rx inphase/quadrature (I/Q) signal **318**. The 4Rx inphase/quadrature (I/Q) signal **318** may include a secondary signal **278** from the third band **276**.

A routing **543** from the fourth antenna **309** through the fifth receiver (5Rx) **347** to obtain the 5Rx inphase/quadrature (I/Q) signal **319** is also shown. The routing **543** may be referred to as a second secondary routing. For example, the second secondary routing may correspond to a non-cellular signal such as a global positioning system (GPS) or Wi-Fi signal. The second secondary routing may correspond to the same non-cellular (i.e. secondary) technology as the first secondary routing. For example, both the first secondary routing and the second secondary routing may correspond to a global positioning system (GPS) signal. In another example, the first secondary routing may correspond to a global positioning system (GPS) signal while the second secondary routing may correspond to a Wi-Fi signal. In this manner, the single-chip carrier aggregation receiver architecture **125** may be used to employ one or more secondary signals **278** when carrier aggregation mode is idle. In addition, when multiple receivers on the transceiver chip **310** are processing the secondary signal **278**, secondary diversity may be achieved.

The routing **543** may pass through the sixth surface acoustic wave (SAW) filter **334f** and the first 5Rx low noise amplifier (LNA) **355a**. The 5Rx inphase/quadrature (I/Q) signal **319** may include secondary signal **278** from the third band **276**.

In some configurations, the routing **541** through the fourth receiver (4Rx) **346** may be driven by the 2Rx voltage controlled oscillator (VCO) **361** from the second receiver (2Rx) **342** and the routing **543** through the fifth receiver (5Rx) **347** may be driven by the 5Rx voltage controlled oscillator (VCO) **363** from the fifth receiver (5Rx) **347**. Both the 2Rx voltage

controlled oscillator (VCO) 361 and the 5Rx voltage controlled oscillator (VCO) 363 may be tuned to the secondary frequency. In some instances, when the 2Rx voltage controlled oscillator (VCO) 361 and the 5Rx voltage controlled oscillator (VCO) 363 are tuned to the same frequency, they may interfere with each other. For example, the voltage controlled oscillators (VCOs) may pull each other away from the desired frequency.

When running in secondary diversity mode, carrier aggregation receivers 3Rx 344 and/or 4Rx 346 may not be able to be used for secondary diversity. Likewise, when the transceiver chip 210 is running in secondary diversity mode, the transceiver chip 210 may not be able to concurrently run in simultaneous hybrid dual receiver (SHDR). In other words, in some configurations, operating in secondary diversity mode may be mutually exclusive from operating in simultaneous hybrid dual receiver (SHDR) mode and/or carrier aggregation mode.

FIG. 6 is a block diagram illustrating a single-chip carrier aggregation receiver architecture 325 that reuses a carrier aggregation receiver to achieve secondary diversity. The single-chip carrier aggregation receiver architecture 325 of FIG. 6 may be the single-chip carrier aggregation receiver architecture 325 of FIG. 3. For simplicity, FIG. 6 only illustrates the third antenna 307, fourth antenna 309, fourth receiver (4Rx) 346 and fifth receiver (5Rx) 347 of the transceiver chip 310. However, it should be appreciated that the transceiver chip 310 of FIG. 6 may include some or all of the other components shown and described in connection with the transceiver chip 310 of FIG. 3.

In some configurations, when not in carrier aggregation mode, the fourth receiver (4Rx) 346 may be idle. In other words, the fourth receiver (4Rx) 346 is not being used for carrier aggregation. Similarly, the fourth receiver (4Rx) 346 may be idle when the transceiver chip 310 is not in simultaneous hybrid dual receiver (SHDR) mode. In these instances, the fourth receiver (4Rx) 346 may be reused for secondary diversity. In this manner, the fourth receiver (4Rx) 346 may share the frontend, mixer 356d, divider 358d and the 4Rx baseband filter (BBF) 364d from the carrier aggregation path to achieve secondary diversity.

The third antenna 307 and the fourth antenna 309 may receive a secondary signal 278. For example, the signal may be a global navigation satellite system (GNSS), global positioning system (GPS), Wi-Fi or Bluetooth signal. For instance, the secondary signal 278 may be a global positioning system (GPS) signal received on a Personal Digital Cellular (PDC) band. In another instance, the secondary signal 278 may be a Wi-Fi or a Bluetooth signal received on a 2.4 gigahertz (GHz) band.

A routing 645 from the third antenna 307 through the fourth receiver (4Rx) 346 to obtain the 4Rx inphase/quadrature (I/Q) signal 318 is shown. The routing 645 may be referred to as a first secondary routing. The routing 645 may pass through the fifth surface acoustic wave (SAW) filter 334e and the third 4Rx low noise amplifier (LNA) 354c. The routing 645 may pass through the mixer 356d. The mixer 356d may receive input from the Div stage 358d. The Div stage 358d may receive a downconverting frequency generated by the 5Rx voltage controlled oscillator (VCO) 363 of the fifth receiver (5Rx) 347. The routing 645 may pass through the 4Rx baseband filter (BBF) 364d to form a 4Rx inphase/quadrature (I/Q) signal 318. The 4Rx inphase/quadrature (I/Q) signal 318 may include a secondary signal 278 from the third band 276.

A routing 643 from the fourth antenna 309 through the fifth receiver (5Rx) 347 to obtain the 5Rx inphase/quadrature (I/Q)

signal 319 is also shown. The 5Rx inphase/quadrature (I/Q) signal 319 may include a secondary signal 278 from the third band 276.

The routing 643 may be referred to as a second secondary routing. The routing 643 may pass through the sixth surface acoustic wave (SAW) filter 334f and the first 5Rx low noise amplifier (LNA) 355a. In some embodiments, as shown in FIG. 6, the routing 643 may pass through a seventh surface acoustic wave (SAW) filter 634g and a second 5Rx low noise amplifier (LNA) 655b. The seventh surface acoustic wave (SAW) filter 634g and the second 5Rx low noise amplifier (LNA) 655b may provide additional signal filtering that may result in a higher signal performance.

Both the fourth receiver (4Rx) 346 and the fifth receiver (5Rx) 347 may be driven by the same synthesizer (e.g., the 5Rx voltage controlled oscillator (VCO) 363 and the phase lock loop (PLL) 362c from the fifth receiver (5Rx) 347). In this manner, multiple synthesizers are not competing and pulling against each other causing the frequency to stray or other errors.

FIG. 7 is a block diagram illustrating a single-chip carrier aggregation receiver architecture 325 that reuses a receiver front end and a baseband filter (BBF) of a carrier aggregation receiver to achieve secondary diversity. The single-chip carrier aggregation receiver architecture 325 of FIG. 7 may be the single-chip carrier aggregation receiver architecture 325 of FIG. 3. For simplicity, FIG. 7 only illustrates the third antenna 307, fourth antenna 309, fourth receiver (4Rx) 346 and fifth receiver (5Rx) 347 of the transceiver chip 310. However, it should be appreciated that the transceiver chip 310 of FIG. 7 may include some or all of the other components shown and described in connection with the transceiver chip 310 of FIG. 3.

The third antenna 307 and the fourth antenna 309 may receive a secondary signal 278. For example, the signal may be a global navigation satellite system (GNSS), global positioning system (GPS) or Wi-Fi signal. In some configurations, the fourth receiver (4Rx) 346 may share the low noise amplifier (LNA) 354 and the 4Rx baseband filter (BBF) 364d from the carrier aggregation path to achieve secondary diversity.

The fourth receiver (4Rx) 346 of FIG. 7 may include a mixer 756f and a Div stage 758f that were not included in the fourth receiver (4Rx) 346 of FIG. 3.

A routing 749 from the third antenna 307 through the fourth receiver (4Rx) 346 to obtain the 4Rx inphase/quadrature (I/Q) signal 318 is shown. The routing 749 may be referred to as a first secondary routing. The routing 749 may pass through the fifth surface acoustic wave (SAW) filter 334e and the third 4Rx low noise amplifier (LNA) 354c. The routing 749 may pass through the mixer 756f. The mixer 756f may receive input from the Div stage 758f. The mixer 756f (e.g., downconverter) and the Div stage 758f may be separate from the mixer 356d and the Div stage 358d used for carrier aggregation in the fourth receiver (4Rx) 346. In this manner, power consumption may be reduced by reducing the power necessary to drive the mixer 756f.

The Div stage 758f may receive a downconverting frequency generated by the 5Rx voltage controlled oscillator (VCO) 363 of the fifth receiver (5Rx) 347. The routing 749 may pass through the 4Rx baseband filter (BBF) 364d to form a 4Rx inphase/quadrature (I/Q) signal 318. The 4Rx inphase/quadrature (I/Q) signal 318 may include a secondary signal 278 from the third band 276.

A routing 743 from the fourth antenna 309 through the fifth receiver (5Rx) 347 to obtain the 5Rx inphase/quadrature (I/Q)

signal **319** is also shown. The 5Rx inphase/quadrature (I/Q) signal **319** may include a secondary signal **278** from the third band **276**.

The routing **743** may be referred to as a second secondary routing. The routing **743** may pass through the sixth surface acoustic wave (SAW) filter **334f** and the first 5Rx low noise amplifier (LNA) **355a**.

FIG. **8** is another block diagram illustrating a single-chip carrier aggregation receiver architecture **325** that reuses a baseband filter (BBF) of a carrier aggregation receiver to achieve secondary diversity. As with FIG. **6** and FIG. **7**, FIG. **8** illustrates only the third antenna **307**, fourth antenna **309**, fourth receiver (4Rx) **346** and fifth receiver (5Rx) **347** of the transceiver chip **310**. However, it should be appreciated that the transceiver chip **310** of FIG. **8** may include some or all of the other components shown and described in connection with the transceiver chip **310** of FIG. **3**.

The third antenna **307** and the fourth antenna **309** may receive a secondary signal **278**. For example, the secondary signal **278** may be a global navigation satellite system (GNSS), global positioning system (GPS) or Wi-Fi signal. In one configuration, the secondary signal **278** may be a global positioning system (GPS) signal received on a Personal Digital Cellular (PDC) band.

A routing **853** from the third antenna **307** through the fifth receiver (5Rx) **346** to obtain the 5Rx inphase/quadrature (I/Q) signal **319** is shown. The routing **853** may be referred to as a first secondary routing. The routing **853** may pass through the fifth surface acoustic wave (SAW) filter **334e** and the first 5Rx low noise amplifier (LNA) **355a**. The routing **853** may pass through the mixer **856f**. The mixer **856f** may receive input from the Div stage **858f**. The mixer **856f** (e.g., downconverter) and the Div stage **858f** may be separate from the mixer **356e** and the Div stage **358e** used in the fifth receiver (5Rx) **347**.

The Div stage **858f** may receive a downconverting frequency generated by the 5Rx voltage controlled oscillator (VCO) **363** from the fifth receiver (5Rx) **347**. The routing **853** may also pass through the 5Rx baseband filter (BBF) **364e** to form a 5Rx inphase/quadrature (I/Q) signal **319**. The 5Rx inphase/quadrature (I/Q) signal **319** may include a secondary signal **278** from the third band **276**. In this manner, the fourth receiver (4Rx) **346** may share the 4Rx baseband filter (BBF) **364d** from the carrier aggregation path to achieve secondary diversity.

A routing **851** from the fourth antenna **309** through the fifth receiver (5Rx) **347** to obtain the 4Rx inphase/quadrature (I/Q) signal **318** is also shown. The routing **851** may be referred to as a second secondary routing. The routing **851** may pass through the sixth surface acoustic wave (SAW) filter **334f** and the first 5Rx low noise amplifier (LNA) **355a**. The routing **851** may then pass through the 4Rx baseband filter (BBF) **364d** to form a 4Rx inphase/quadrature (I/Q) signal **318**. In this manner, the 4Rx baseband filter (BBF) **364d** of the fourth receiver (4Rx) **346** is reused for secondary diversity. The 4Rx inphase/quadrature (I/Q) signal **318** may include a secondary signal **278** from the third band **276**.

FIG. **9** is a block diagram illustrating one configuration of a baseband digital modem **922** used for secondary (e.g., global navigation satellite system (GNSS)) diversity. The baseband digital modem **922** may be part of the transceiver chip **310** or a separate component from the transceiver chip **310**. The baseband digital modem **922** may be one configurations of the baseband digital modem described in connection with the baseband digital modem **122** of FIG. **1**.

The baseband digital modem **922** may include a first global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955a**, a first baseband processor **957a**, a global

navigation satellite system (GNSS) controller **959**, a second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b**, a second baseband processor **957b**, a wireless wide area network (WWAN) analog-to-digital converter (ADC) **969**, a wireless wide area network (WWAN) digital front end (DFE) **971** and a wireless wide area network (WWAN) sample memory **973**. The baseband digital modem **922** may receive a 4Rx inphase/quadrature (I/Q) signal **918** and a 5Rx inphase/quadrature (I/Q) signal **919**. The global navigation satellite system (GNSS) controller **959** may employ multiple digital signals to obtain a more accurate determination of the wireless communication device **104**.

The first global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955a** may receive the 4Rx I/Q signal **918**. The first global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955a** may convert the 4Rx inphase/quadrature (I/Q) signal **918** from an analog signal to a digital signal. The digital signal may pass through the first baseband processor **957a** and into the global navigation satellite system (GNSS) controller **959**. A global navigation satellite system (GNSS) may include global positioning systems (GPS), satellite based augmentation systems (SBAS) and/or ground based augmentation systems (GBAS). The global navigation satellite system (GNSS) controller **959** may determine the location of the wireless communication device **104** based on the digital signal.

The 5Rx inphase/quadrature (I/Q) signal **919** may be passed through the second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b** to obtain a digital signal. The digital signal may be passed through the second baseband processor **957b** before being input into the global navigation satellite system (GNSS) controller **959**. By obtaining multiple secondary signals (e.g., global positioning system (GPS) signals), the global navigation satellite system (GNSS) controller **959** may have improved accuracy.

The 5Rx inphase/quadrature (I/Q) signal **919** may also be provided to the wireless wide area network (WWAN) analog-to-digital converter (ADC) **969**. The output of the wireless wide area network (WWAN) analog-to-digital converter (ADC) **969** may be passed through the wireless wide area network (WWAN) digital front end (DFE) **971** and stored in the wireless wide area network (WWAN) sample memory **973**. The second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b** and the wireless wide area network (WWAN) analog-to-digital converter (ADC) **969** may share pins for the 5Rx inphase/quadrature (I/Q) signal **919**.

In some configurations, the second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b** may be added to a known baseband digital modem configurations. In this configuration, the second baseband processor **957b** may already exist on the baseband digital modem **922** and may be reused to process the digital output from the second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b**. Adding the second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b** may require a minor increase (e.g., 28 nanometers (nm)) in die size on the baseband digital modem **922** and the second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b** may be limited to non-terrestrial signals. However, power consumption may be reduced in obtaining secondary diversity using the baseband digital modem **922** as compared to known approaches for obtaining secondary diversity.

FIG. **10** is a block diagram illustrating another configuration of a baseband digital modem **1022** used for secondary (e.g., global navigation satellite system (GNSS)) diversity.

The baseband digital modem **1022** may be one configurations of the baseband digital modem **112** described in connection with FIG. 1. The baseband digital modem **1022** may include a global navigation satellite system (GNSS) analog-to-digital converter (ADC) **1055**, a first baseband processor **1057a**, a global navigation satellite system (GNSS) controller **1059**, a second baseband processor **1057b**, a wireless wide area network (WWAN) analog-to-digital converter (ADC) **1069**, a wireless wide area network (WWAN) digital front end (DFE) **1071** and a wireless wide area network (WWAN) sample memory **1073**. The baseband digital modem **1022** may receive the 4Rx inphase/quadrature (I/Q) signal **1018** and the 5Rx inphase/quadrature (I/Q) signal **1017**.

The first global navigation satellite system (GNSS) analog-to-digital converter (ADC) **1055** may convert the 4Rx inphase/quadrature (I/Q) signal **1018** to a digital signal. The digital signal may be passed through the first baseband processor **1057a** to the global navigation satellite system (GNSS) controller **1059**.

The wireless wide area network (WWAN) analog-to-digital converter (ADC) **1069** may convert the 5Rx inphase/quadrature (I/Q) signal **1017** to a digital signal. The wireless wide area network (WWAN) analog-to-digital converter (ADC) **1069** may use the same clock as the global navigation satellite system (GNSS) analog-to-digital converter (ADC) **1055** or the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1069** may use a standard wireless wide area network (WWAN) analog-to-digital converter (ADC) clock.

The output of the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1069** may be passed through the wireless wide area network (WWAN) digital front end (DFE) **1071** and stored in the wireless wide area network (WWAN) sample memory **1073**. The output of the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1069** may also be passed through the second baseband processor **1057b** and be provided to the global navigation satellite system (GNSS) controller **1059**.

In this configuration, the die size may remain the same because no additional components are required compared to known baseband digital modem configurations. However, in this configuration, the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1069** may consume more power than the second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b** described in connection with FIG. 9.

FIG. 11 is a block diagram illustrating yet another configuration of a baseband digital modem **1122** used for secondary (e.g., global navigation satellite system (GNSS)) diversity. The baseband digital modem **1122** may be one configurations of the baseband digital modem **122** described in connection with FIG. 1. The baseband digital modem **1122** may include a global navigation satellite system (GNSS) analog-to-digital converter (ADC) **1155**, a first baseband processor **1157a**, a global navigation satellite system (GNSS) controller **1159**, a second baseband processor **1157b**, a wireless wide area network (WWAN) analog-to-digital converter (ADC) **1169**, a wireless wide area network (WWAN) digital front end (DFE) **1171** and a wireless wide area network (WWAN) sample memory **1173**. The baseband digital modem **1122** may also receive inputs from the 4Rx inphase/quadrature (I/Q) signal **1118** and the 5Rx inphase/quadrature (I/Q) signal **1117**.

The first global navigation satellite system (GNSS) analog-to-digital converter (ADC) **1155** may convert the 4Rx inphase/quadrature (I/Q) signal **1118** from an analog signal and may output a first digital signal.

may pass through the first baseband processor **1157a** and into the global navigation satellite system (GNSS) controller **1159**.

The wireless wide area network (WWAN) analog-to-digital converter (ADC) **1169** may convert the 5Rx inphase/quadrature (I/Q) signal **1117** to a second digital signal. The second digital signal may pass through the wireless wide area network (WWAN) digital front end (DFE) **1171** and be stored in wireless wide area network (WWAN) sample memory **1173**. Additionally, the second digital signal may pass through the wireless wide area network (WWAN) digital front end (DFE) **1171** and the second baseband processor **1157b** before being input into the global navigation satellite system (GNSS) controller **1159**.

In this configuration, the existing components may be reused, such as the wireless wide area network (WWAN) digital front end (DFE) **1171**. For example, the gain control and the DC offset from the wireless wide area network (WWAN) radio frequency (RF) diver stack of the wireless wide area network (WWAN) digital front end (DFE) **1171** may be reused. Additionally, larger signals, such as NextNav, may be handled. However, this configuration may consume more power than the second global navigation satellite system (GNSS) analog-to-digital converter (ADC) **955b** described in connection with FIG. 9.

FIG. 12 is a block diagram illustrating one configuration of a baseband digital modem **1222** used for secondary (e.g., wireless local area network (WLAN)) diversity. The baseband digital modem **1222** may be part of the transceiver chip **310** or a separate component from the transceiver chip **310**. The baseband digital modem **1222** may be one configurations of the baseband digital modem described in connection with the baseband digital modem **122** of FIG. 1.

The baseband digital modem **1222** may include a first wireless local area network (WLAN) analog-to-digital converter (ADC) **1269a**, a second wireless local area network (WLAN) analog-to-digital converter (ADC) **1269b**, a wireless wide area network (WWAN) analog-to-digital converter (ADC) **1269c**, a first wireless local area network (WLAN) digital front end (DFE) **1271a**, a second wireless local area network (WLAN) digital front end (DFE) **1271b**, a wireless wide area network (WWAN) digital front end (DFE) **1271c**, a wireless local area network (WLAN) controller **1275** and a wireless wide area network (WWAN) sample memory **1273**. The baseband digital modem **1222** may receive a 4Rx inphase/quadrature (I/Q) signal **1218** and a 5Rx inphase/quadrature (I/Q) signal **1219**. The wireless local area network (WLAN) controller **1275** may employ multiple digital signals to obtain a more accurate determination of the wireless communication device **104**.

The first wireless local area network (WLAN) analog-to-digital converter (ADC) **1269a** may receive the 4Rx I/Q signal **1218**. The first wireless local area network (WLAN) analog-to-digital converter (ADC) **1269a** may convert the 4Rx inphase/quadrature (I/Q) signal **1218** from an analog signal to a digital signal. The digital signal may pass through the first wireless local area network (WLAN) digital front end (DFE) **1271a** and into the wireless local area network (WLAN) controller **1275**. The wireless local area network (WLAN) controller **1275** may obtain data for the wireless communication device **104** based on the digital signal.

The 5Rx inphase/quadrature (I/Q) signal **1219** may be passed through the second wireless local area network (WLAN) analog-to-digital converter (ADC) **1269b** to obtain a digital signal. The digital signal may be passed through the second wireless local area network (WLAN) digital front end (DFE) **1271b** before being input into the wireless local area

network (WLAN) controller **1275**. By obtaining multiple secondary signals (e.g., wireless local area network (WLAN)), the wireless local area network (WLAN) controller **1275** may have improved accuracy.

The 5Rx inphase/quadrature (I/Q) signal **1219** may also be provided to the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1269c**. The output of the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1269c** may be passed through the wireless wide area network (WWAN) digital front end (DFE) **1271c** and stored in the wireless wide area network (WWAN) sample memory **1273**. The second wireless local area network (WLAN) analog-to-digital converter (ADC) **1269b** and the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1269c** may share pins for the 5Rx inphase/quadrature (I/Q) signal **1219**.

FIG. **13** is a block diagram illustrating another configuration of a baseband digital modem **1322** used for secondary (e.g., wireless local area network (WLAN)) diversity. The baseband digital modem **1322** may be one configurations of the baseband digital modem **112** described in connection with FIG. **1**.

The baseband digital modem **1322** may include a first wireless local area network (WLAN) analog-to-digital converter (ADC) **1369a**, a wireless wide area network (WWAN) analog-to-digital converter (ADC) **1369b**, a first wireless local area network (WLAN) digital front end (DFE) **1371a**, a second wireless local area network (WLAN) digital front end (DFE) **1371b**, a wireless wide area network (WWAN) digital front end (DFE) **1371c**, a wireless local area network (WLAN) controller **1375** and a wireless wide area network (WWAN) sample memory **1373**. The baseband digital modem **1322** may receive a 4Rx inphase/quadrature (I/Q) signal **1318** and a 5Rx inphase/quadrature (I/Q) signal **1319**.

The first wireless local area network (WLAN) analog-to-digital converter (ADC) **1369a** may convert the 4Rx inphase/quadrature (I/Q) signal **1318** to a digital signal. The digital signal may be passed through the first wireless local area network (WLAN) digital front end (DFE) **1371a** to the wireless local area network (WLAN) controller **1375**.

The wireless wide area network (WWAN) analog-to-digital converter (ADC) **1369b** may convert the 5Rx inphase/quadrature (I/Q) signal **1319** to a digital signal. In some configurations, the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1369b** may use the same clock as the first wireless local area network (WLAN) analog-to-digital converter (ADC) **1369a**.

The output of the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1369b** may be passed through the second wireless local area network (WLAN) digital front end (DFE) **1371b** and be provided to the wireless local area network (WLAN) controller **1375**. The output of the wireless wide area network (WWAN) analog-to-digital converter (ADC) **1369b** may also be passed through the wireless wide area network (WWAN) digital front end (DFE) **1371c** and stored in the wireless wide area network (WWAN) sample memory **1373**. However, while the baseband digital modem **1322** of FIG. **13** may require less elements than the baseband digital modem **1222** described in connection with FIG. **12**, the baseband digital modem **1322** of FIG. **13** may consume more power than the baseband digital modem **1222** described in connection with FIG. **12**.

FIG. **14** is a block diagram illustrating yet another configuration of a baseband digital modem **1422** used for secondary (e.g., wireless local area network (WLAN)) diversity. The

baseband digital modem **1422** may be one configurations of the baseband digital modem **122** described in connection with FIG. **1**.

The baseband digital modem **1422** may include a wireless local area network (WLAN) analog-to-digital converter (ADC) **1469a**, a wireless wide area network (WWAN) analog-to-digital converter (ADC) **1469b**, a wireless local area network (WLAN) digital front end (DFE) **1471a**, a wireless wide area network (WWAN) digital front end (DFE) **1471b**, a wireless local area network (WLAN) controller **1475** and a wireless wide area network (WWAN) sample memory **1473**. The baseband digital modem **1422** may receive a 4Rx inphase/quadrature (I/Q) signal **1418** and a 5Rx inphase/quadrature (I/Q) signal **1419**.

The wireless local area network (WLAN) analog-to-digital converter (ADC) **1469a** may convert the 4Rx inphase/quadrature (I/Q) signal **1418** from an analog signal and may output a first digital signal. The first digital signal may pass through the wireless local area network (WLAN) digital front end (DFE) **1471a** and into the wireless local area network (WLAN) controller **1475**.

The wireless wide area network (WWAN) analog-to-digital converter (ADC) **1469b** may convert the 5Rx inphase/quadrature (I/Q) signal **1419** to a second digital signal. The second digital signal may pass through the wireless wide area network (WWAN) digital front end (DFE) **1471b** before being input into the wireless local area network (WLAN) controller **1475**. Additionally, the second digital signal may pass through the wireless wide area network (WWAN) digital front end (DFE) **1471b** and be stored in wireless wide area network (WWAN) sample memory **1473**.

In this configuration, the existing components may be reused, such as the wireless wide area network (WWAN) digital front end (DFE) **1471b**. For example, the gain control and the DC offset from the wireless wide area network (WWAN) radio frequency (RF) diver stack of the wireless wide area network (WWAN) digital front end (DFE) **1471b** may be reused. Additionally, larger signals may be handled. However, this configuration may consume more power than the baseband digital modem **1222** described in connection with FIG. **12**.

FIG. **15** illustrates certain components that may be included within a wireless communication device **1504**. The wireless communication device **1504** may be an access terminal, a mobile station, a user equipment (UE), etc. The wireless communication device **1504** includes a processor **1573**. The processor **1573** may be a general purpose single- or multi-chip microprocessor (e.g., an ARM), a special purpose microprocessor (e.g., a digital signal processor (DSP)), a microcontroller, a programmable gate array, etc. The processor **1573** may be referred to as a central processing unit (CPU). Although just a single processor **1573** is shown in the wireless communication device **1504** of FIG. **15**, in an alternative configuration, a combination of processors (e.g., an ARM and DSP) could be used.

The wireless communication device **1504** also includes memory **1575**. The memory **1575** may be any electronic component capable of storing electronic information. The memory **1575** may be embodied as random access memory (RAM), read-only memory (ROM), magnetic disk storage media, optical storage media, flash memory devices in RAM, on-board memory included with the processor, EPROM memory, EEPROM memory, registers and so forth, including combinations thereof.

Data **1577a** and instructions **1579a** may be stored in the memory **1575**. The instructions **1579a** may be executable by the processor **1573** to implement the methods disclosed

herein. Executing the instructions **1579a** may involve the use of the data **1577a** that is stored in the memory **1595**. When the processor **1573** executes the instructions **1579**, various portions of the instructions **1579b** may be loaded onto the processor **1573** and various pieces of data **1577b** may be loaded onto the processor **1573**.

The wireless communication device **1504** may also include a transmitter **1581** and a receiver **1583** to allow transmission and reception of signals to and from the wireless communication device **1504** via a first antenna **1587a**, a second antenna **1587b**, a third antenna **1587c** and fourth antenna **1587d**. The transmitter **1581** and receiver **1583** may be collectively referred to as a transceiver **1585**. The wireless communication device **1504** may also include (not shown) multiple transmitters, additional antennas, multiple receivers and/or multiple transceivers.

The wireless communication device **1504** may include a digital signal processor (DSP) **1591**. The wireless communication device **1504** may also include a communications interface **1593**. The communications interface **1593** may allow a user to interact with the wireless communication device **1504**.

The various components of the wireless communication device **1504** may be coupled together by one or more buses, which may include a power bus, a control signal bus, a status signal bus, a data bus, etc. For the sake of clarity, the various buses are illustrated in FIG. **15** as a bus system **1589**.

The term “determining” encompasses a wide variety of actions and, therefore, “determining” can include calculating, computing, processing, deriving, investigating, looking up (e.g., looking up in a table, a database or another data structure), ascertaining and the like. Also, “determining” can include receiving (e.g., receiving information), accessing (e.g., accessing data in a memory) and the like. Also, “determining” can include resolving, selecting, choosing, establishing and the like.

The phrase “based on” does not mean “based only on,” unless expressly specified otherwise. In other words, the phrase “based on” describes both “based only on” and “based at least on.”

The term “processor” should be interpreted broadly to encompass a general purpose processor, a central processing unit (CPU), a microprocessor, a digital signal processor (DSP), a controller, a microcontroller, a state machine and so forth. Under some circumstances, a “processor” may refer to an application specific integrated circuit (ASIC), a programmable logic device (PLD), a field programmable gate array (FPGA), etc. The term “processor” may refer to a combination of processing devices, e.g., a combination of a DSP and a microprocessor, a plurality of microprocessors, one or more microprocessors in conjunction with a DSP core, or any other such configuration.

The term “memory” should be interpreted broadly to encompass any electronic component capable of storing electronic information. The term memory may refer to various types of processor-readable media such as random access memory (RAM), read-only memory (ROM), non-volatile random access memory (NVRAM), programmable read-only memory (PROM), erasable programmable read-only memory (EPROM), electrically erasable PROM (EEPROM), flash memory, magnetic or optical data storage, registers, etc. Memory is said to be in electronic communication with a processor if the processor can read information from and/or write information to the memory. Memory that is integral to a processor is in electronic communication with the processor.

The terms “instructions” and “code” should be interpreted broadly to include any type of computer-readable statement(s). For example, the terms “instructions” and “code”

may refer to one or more programs, routines, sub-routines, functions, procedures, etc. “Instructions” and “code” may comprise a single computer-readable statement or many computer-readable statements.

The functions described herein may be implemented in software or firmware being executed by hardware. The functions may be stored as one or more instructions on a computer-readable medium. The terms “computer-readable medium” or “computer-program product” refers to any tangible storage medium that can be accessed by a computer or a processor. By way of example, and not limitation, a computer-readable medium may include RAM, ROM, EEPROM, CD-ROM or other optical disk storage, magnetic disk storage or other magnetic storage devices, or any other medium that can be used to carry or store desired program code in the form of instructions or data structures and that can be accessed by a computer. Disk and disc, as used herein, includes compact disc (CD), laser disc, optical disc, digital versatile disc (DVD), floppy disk and Blu-ray® disc where disks usually reproduce data magnetically, while discs reproduce data optically with lasers. It should be noted that a computer-readable medium may be tangible and non-transitory. The term “computer-program product” refers to a computing device or processor in combination with code or instructions (e.g., a “program”) that may be executed, processed or computed by the computing device or processor. As used herein, the term “code” may refer to software, instructions, code or data that is/are executable by a computing device or processor.

Software or instructions may also be transmitted over a transmission medium. For example, if the software is transmitted from a website, server, or other remote source using a coaxial cable, fiber optic cable, twisted pair, digital subscriber line (DSL), or wireless technologies such as infrared, radio and microwave, then the coaxial cable, fiber optic cable, twisted pair, DSL, or wireless technologies such as infrared, radio and microwave are included in the definition of transmission medium.

The methods disclosed herein comprise one or more steps or actions for achieving the described method. The method steps and/or actions may be interchanged with one another without departing from the scope of the claims. In other words, unless a specific order of steps or actions is required for proper operation of the method that is being described, the order and/or use of specific steps and/or actions may be modified without departing from the scope of the claims.

Further, it should be appreciated that modules and/or other appropriate means for performing the methods and techniques described herein, such as those illustrated by FIG. **4**, can be downloaded and/or otherwise obtained by a device. For example, a device may be coupled to a server to facilitate the transfer of means for performing the methods described herein. Alternatively, various methods described herein can be provided via a storage means (e.g., random access memory (RAM), read-only memory (ROM), a physical storage medium such as a compact disc (CD) or floppy disk, etc.), such that a device may obtain the various methods upon coupling or providing the storage means to the device. Moreover, any other suitable technique for providing the methods and techniques described herein to a device can be utilized.

It is to be understood that the claims are not limited to the precise configuration and components illustrated above. Various modifications, changes and variations may be made in the arrangement, operation and details of the systems, methods and apparatus described herein without departing from the scope of the claims.

What is claimed is:

1. A wireless communication device configured for receiving multiple signals, comprising:

a single-chip carrier aggregation receiver architecture that comprises:

- a first antenna;
- a second antenna;
- a third antenna;
- a fourth antenna; and

a transceiver chip, wherein the transceiver chip comprises multiple carrier aggregation receivers, and wherein the single-chip carrier aggregation receiver architecture reuses at least one of the carrier aggregation receivers for secondary diversity.

2. The wireless communication device of claim 1, wherein the multiple carrier aggregation receivers comprise:

- a first receiver;
- a second receiver;
- a third receiver; and
- a fourth receiver, and wherein the transceiver chip further comprises:
 - a transmitter; and
 - a fifth receiver.

3. The wireless communication device of claim 2, wherein the multiple carrier aggregation receivers each comprise multiple low noise amplifiers, and wherein the fifth receiver comprises multiple low noise amplifiers.

4. The wireless communication device of claim 2, wherein the fifth receiver is a non-carrier aggregation receiver.

5. The wireless communication device of claim 2, wherein the fifth receiver is a non-simultaneous hybrid dual receiver.

6. The wireless communication device of claim 2, wherein the fifth receiver is a global navigation satellite system receiver.

7. The wireless communication device of claim 2, wherein the fifth receiver is a Bluetooth receiver.

8. The wireless communication device of claim 2, wherein the fifth receiver is a Wi-Fi receiver.

9. The wireless communication device of claim 2, wherein a first secondary routing is used from the third antenna through the fourth receiver to obtain a fourth Rx inphase/quadrature signal, and wherein a second secondary routing is used from the fourth antenna through the fifth receiver to obtain a fifth Rx inphase/quadrature signal.

10. The wireless communication device of claim 9, wherein the first secondary routing passes through a first 4Rx low noise amplifier, and wherein the second secondary routing passes through a first 5Rx low noise amplifier and a second 5Rx low noise amplifier.

11. The wireless communication device of claim 9, wherein the first receiver comprises a first mixer, wherein the second receiver comprises a second mixer, wherein the third receiver comprises a third mixer, wherein the fourth receiver comprises a fourth mixer, and wherein the fifth receiver comprises a fifth mixer.

12. The wireless communication device of claim 11 wherein the first secondary routing passes through the fourth mixer.

13. The wireless communication device of claim 12, wherein the fourth mixer is driven by a voltage controlled oscillator on the second receiver.

14. The wireless communication device of claim 12, wherein the fourth mixer is driven by a voltage controlled oscillator on the fifth receiver.

15. The wireless communication device of claim 11, further comprising a sixth mixer on the fourth receiver, wherein the sixth mixer is driven by a voltage controlled oscillator on the fifth receiver.

16. The wireless communication device of claim 11, further comprising a sixth mixer on the fifth receiver, and wherein the sixth mixer is driven by a voltage controlled oscillator on the fifth receiver.

17. The wireless communication device of claim 9, wherein the first secondary routing passes through a first 5RX low noise amplifier, and wherein the second secondary routing passes through a second 5RX low noise amplifier.

18. The wireless communication device of claim 9, wherein the fourth Rx inphase/quadrature signal and the fifth Rx inphase/quadrature signal pass through a baseband digital modem.

19. The wireless communication device of claim 18, wherein the baseband digital modem comprises:

- a first analog-to-digital converter;
- a first baseband processor;
- a controller;
- a second analog-to-digital converter;
- a digital front end; and
- a sample memory.

20. The wireless communication device of claim 19, wherein the first analog-to-digital converter is a global navigation satellite system analog-to-digital converter, wherein the controller is a global navigation satellite system controller, wherein the second analog-to-digital converter is a wireless wideband area network analog-to-digital converter, wherein the digital front end is a wireless wideband area network digital front end, and wherein the sample memory is a wideband area network sample memory.

21. The wireless communication device of claim 19, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first baseband processor and the controller, wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through a third analog-to-digital converter, a second baseband processor and the controller.

22. The wireless communication device of claim 21, wherein the third analog-to-digital converter is a global navigation satellite system analog-to-digital converter.

23. The wireless communication device of claim 19, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first baseband processor and the controller, wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, a second baseband processor and the controller.

24. The wireless communication device of claim 19, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first baseband processor and the controller, wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the digital front end, a second baseband processor and the controller.

27

25. The wireless communication device of claim 18, wherein the baseband digital modem comprises:

- a first analog-to-digital converter;
- a first digital front end;
- a controller;
- a second analog-to-digital converter;
- a second digital front end; and
- a sample memory.

26. The wireless communication device of claim 25, wherein the first analog-to-digital converter is a wireless local area network analog-to-digital converter, wherein the first digital front end is a wireless local area network digital front end, wherein the controller is a wireless local area network controller, wherein the second analog-to-digital converter is a wireless wide area network analog-to-digital converter, wherein the second digital front end is a wireless wide area network digital front end, and wherein the sample memory is a wide area network sample memory.

27. The wireless communication device of claim 25, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first digital front end and the controller, wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the second digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through a third analog-to-digital converter, a third digital front end and the controller.

28. The wireless communication device of claim 25, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first digital front end and the controller, wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the second digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, a third digital front end and the controller.

29. The wireless communication device of claim 25, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first digital front end and the controller, wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the second digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the second digital front end and the controller.

30. A method for receiving multiple signals using a single-chip carrier aggregation receiver architecture that comprises a first antenna, a second antenna, a third antenna and a fourth antenna, the method comprising:

- receiving a first secondary signal using the third antenna;
- routing the first secondary signal through a fourth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture, wherein the fourth receiver is one of multiple carrier aggregation receivers, and wherein the fourth receiver is reused for secondary diversity;
- receiving a second secondary signal using the fourth antenna; and
- routing the second secondary signal through a fifth receiver on the transceiver chip in the single-chip carrier aggregation receiver architecture.

31. The method of claim 30, wherein the first secondary signal routing is used to obtain a fourth Rx inphase/quadrature signal, and wherein the second secondary signal routing is used to obtain a fifth Rx inphase/quadrature signal.

32. The method of claim 30, wherein the fifth receiver is a non-carrier aggregation receiver.

28

33. The method of claim 30, wherein the fifth receiver is a non-simultaneous hybrid dual receiver.

34. The method of claim 30, wherein the fifth receiver is a global navigation satellite system receiver.

35. The method of claim 30, wherein the fifth receiver is a Bluetooth receiver.

36. The method of claim 30, wherein the fifth receiver is a Wi-Fi receiver.

37. The method of claim 30, wherein the first secondary signal is further routed through a first 4RX low noise amplifier, and wherein the second secondary signal is further routed through a first 5RX low noise amplifier and a second 5RX low noise amplifier.

38. The method of claim 30, wherein the multiple carrier aggregation receivers comprise:

- a first receiver;
- a second receiver;
- a third receiver; and
- the fourth receiver.

39. The method of claim 38, wherein the multiple carrier aggregation receivers each comprise multiple low noise amplifiers, and wherein the fifth receiver comprises multiple low noise amplifiers.

40. The method of claim 38, wherein the multiple carrier aggregation receivers comprise:

- a first mixer on the first receiver;
- a second mixer on the second receiver;
- a third mixer on the third carrier; and
- a fourth mixer on the fourth receiver, and wherein the fifth receiver comprises a fifth mixer.

41. The method of claim 40 wherein the first secondary signal is further routed through the fourth mixer.

42. The method of claim 41, wherein the fourth mixer is driven by a voltage controlled oscillator on the second receiver.

43. The method of claim 41, wherein the fourth mixer is driven by a voltage controlled oscillator on the fifth receiver.

44. The method of claim 40, wherein the transceiver chip further comprises a sixth mixer on the fourth receiver, and wherein the sixth mixer is driven by a voltage controlled oscillator on the fifth receiver.

45. The method of claim 40, wherein the transceiver chip further comprises a sixth mixer on the fifth receiver, and wherein the sixth mixer is driven by a voltage controlled oscillator on the fifth receiver.

46. The method of claim 30, wherein the first secondary signal is routed through a first 5RX low noise amplifier, and wherein the second secondary signal is routed through a second 5RX low noise amplifier.

47. The method of claim 31, wherein the fourth Rx inphase/quadrature signal and the fifth Rx inphase/quadrature signal pass through a baseband digital modem.

48. The method of claim 47, wherein the baseband digital modem comprises:

- a first analog-to-digital converter;
- a first baseband processor;
- a controller;
- a second analog-to-digital converter;
- a digital front end; and
- a sample memory.

49. The method of claim 48, wherein the first analog-to-digital converter is a global navigation satellite system analog-to-digital converter, wherein the controller is a global navigation satellite system controller, wherein the second analog-to-digital converter is a wireless wideband area network analog-to-digital converter, wherein the digital front

end is a wireless wideband area network digital front end, and wherein the sample memory is a wideband area network sample memory.

50. The method of claim 48, wherein the fourth Rx inphase/quadrature signal further passes through the first analog-to-digital converter, the first baseband processor, and the controller, wherein the fifth Rx inphase/quadrature signal further passes through the second analog-to-digital converter, the digital front end, and the sample memory, and wherein the fifth Rx inphase/quadrature signal further passes through a third analog-to-digital converter, a second baseband processor, and the controller.

51. The method of claim 50, wherein the third analog-to-digital converter is a global navigation satellite system analog-to-digital converter.

52. The method of claim 48, wherein the fourth Rx inphase/quadrature signal further passes through the first analog-to-digital converter, the first baseband processor, and the controller, wherein the fifth Rx inphase/quadrature signal further passes through the second analog-to-digital converter, the digital front end, and the sample memory, and wherein the fifth Rx inphase/quadrature signal further passes through the second analog-to-digital converter, a second baseband processor, and the controller.

53. The method of claim 48, wherein the fourth Rx inphase/quadrature signal further passes through the first analog-to-digital converter, the first baseband processor, and the controller, wherein the fifth Rx inphase/quadrature signal further passes through the second analog-to-digital converter, the digital front end, and the sample memory, and wherein the fifth Rx inphase/quadrature signal further passes through the second analog-to-digital converter, the digital front end, a second baseband processor, and the controller.

54. The method of claim 47, wherein the baseband digital modem comprises:

- a first analog-to-digital converter;
- a first digital front end;
- a controller;
- a second analog-to-digital converter;
- a second digital front end; and
- a sample memory.

55. The method of claim 54, wherein the first analog-to-digital converter is a wireless local area network analog-to-digital converter, wherein the first digital front end is a wireless local area network digital front end, wherein the controller is a wireless local area network controller, wherein the second analog-to-digital converter is a wireless wide area network analog-to-digital converter, wherein the second digital front end is a wireless wide area network digital front end, and wherein the sample memory is a wide area network sample memory.

56. The method of claim 54, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first digital front end and the controller, wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the second digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through a third analog-to-digital converter, a third digital front end and the controller.

57. The method of claim 54, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first digital front end and the controller, wherein the fifth Rx inphase/quadrature signal passes through the

second analog-to-digital converter, the second digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, a third digital front end and the controller.

58. The method of claim 54, wherein the fourth Rx inphase/quadrature signal passes through the first analog-to-digital converter, the first digital front end and the controller, wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the second digital front end and the sample memory, and wherein the fifth Rx inphase/quadrature signal passes through the second analog-to-digital converter, the second digital front end and the controller.

59. A computer-program product for receiving multiple signals using a single-chip carrier aggregation receiver architecture that comprises a first antenna, a second antenna, a third antenna and a fourth antenna, the computer-program product comprising a non-transitory computer-readable medium having instructions thereon, the instructions comprising:

- code for causing a wireless communication device to receive a first secondary signal using the third antenna;
- code for causing the wireless communication device to route the first secondary signal through a fourth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture, wherein the fourth receiver is one of multiple carrier aggregation receivers, and wherein the fourth receiver is reused for secondary diversity;
- code for causing the wireless communication device to receive a second secondary signal using the fourth antenna; and
- code for causing the wireless communication device to route the second secondary signal through a fifth receiver on the transceiver chip in the single-chip carrier aggregation receiver architecture.

60. The computer-program product of claim 59, wherein the first secondary signal routing is used to obtain a fourth Rx inphase/quadrature signal, and wherein the second secondary signal routing is used to obtain a fifth Rx inphase/quadrature signal.

61. An apparatus for receiving multiple signals using a single-chip carrier aggregation receiver architecture that comprises a first antenna, a second antenna, a third antenna and a fourth antenna, comprising:

- means for receiving a first secondary signal using the third antenna;
- means for routing the first secondary signal through a fourth receiver on a transceiver chip in the single-chip carrier aggregation receiver architecture, wherein the fourth receiver is one of multiple carrier aggregation receivers, and wherein the fourth receiver is reused for secondary diversity;
- means for receiving a second secondary signal using the fourth antenna; and
- means for routing the second secondary signal through a fifth receiver on the transceiver chip in the single-chip carrier aggregation receiver architecture.

62. The apparatus of claim 61, wherein the first secondary signal routing is used to obtain a fourth Rx inphase/quadrature signal, and wherein the second secondary signal routing is used to obtain a fifth Rx inphase/quadrature signal.
